Helical beta-Peptide Inhibitors of the p53-hDM2 Interaction

**OCR Number:** OCR 1709

**Description:**

Beta-peptide regions of polypeptides can serve as structural mimics of \( \alpha \)-helices in wild type proteins. Because \( \alpha \)-helices of one protein often bind to a target protein in a biological pathway, a polypeptide that contains a helical beta-peptide region can be used to disrupt this type of protein-protein binding. As a result, polypeptides that contain a helical beta-peptide region can be used to treat conditions involving this type of protein-protein binding, such as viral infections and cell proliferation.
